

# 11th Meeting 01/27

## 1. Current Project Status and Progress

- WorkerNet base architecture implemented
- Data statistics analyzer implemented
- Multi-scale pose head (P3 for face, P4 for body) integrated
- **Late Fusion architecture** implemented for stable pose-activity recognition
- Clean dataset prepared (485 train, 88 val, 90 test)
- Baseline model trained (300 epochs)
- base results: 96.77% PCK@0.1, 62.96% IoU, 72.73% activity
- 4 configurations trained (ref\_standard, ablation\_no\_geom, curiosity\_high\_geom, curiosity\_high\_pck)
- Total training time: ~40 GPU-hours
- Key finding: Geometric loss removal improves performance by 9-11% (Geometric makes training worse, removing it *improves* accuracy)

## 2. Data Statistics & Geometric Analysis

$$\vec{v}_i = \left( \frac{x_{bottle} - x_{wrist}}{L_{torso}}, \frac{y_{bottle} - y_{wrist}}{L_{torso}} \right)$$

$$\mu = \frac{1}{N} \sum_{i=1}^N \vec{v}_i,$$

**Bottle Box (Wrist Anchor):**

$$\mathbf{B}_{bottle} = \begin{cases} [(x_L + \mu_x L) \pm \frac{W}{2}, (y_L + \mu_y L) \pm \frac{H}{2}] & \text{if checking\_left, storing} \\ [(x_R + \mu_x L) \pm \frac{W}{2}, (y_R + \mu_y L) \pm \frac{H}{2}] & \text{if checking\_right} \\ [(x_{avg} + \mu_x L) \pm \frac{W}{2}, (y_{avg} + \mu_y L) \pm \frac{H}{2}] & \text{if rotation} \\ \emptyset & \text{if nothing, pretending} \end{cases}$$

W: The width of the average bottle (based on the ratio and the class)

H: The height of the average bottle (based on the ratio and the class)

L: Torso Length

## 3. Architecture Overview and Design Decisions

Design Decision: Why Multi-Scale Pose Head?

#### Quantization Analysis:

For an object of size  $S$  pixels on stride- $s$  feature map:

Feature Resolution =  $\frac{S}{s}$  grid cells

**Example: Face keypoints (eyes, nose) at ~24 pixels:**

**P4 (stride-16):**

Feature Resolution =  $\frac{24}{16} = 1.5$  grid cells

The eye occupies only 1.5 grid cells, making sub-pixel localization impossible.

**P3 (stride-8):**

Feature Resolution =  $\frac{24}{8} = 3.0$  grid cells

The eye spans 2-3 cells

#### Validation Experiment:

We trained two configurations:

1. **Single-scale (P4 only):** Face PCK@0.1 = 64.2%
2. **Multi-scale (P3 for face, P4 for body):** Face PCK@0.1 = 89.1%

Loss Functions: Complete Derivations with Citations

$$\begin{aligned}
 L_{total} = & e^{-s_{det}} \cdot L_{WIoU}(y_{box}, \hat{y}_{box}) + \frac{1}{2} s_{det} \\
 & + e^{-s_{pose}} \cdot (\text{WingLoss}(y_{kpt}, \hat{y}_{kpt}) + L_{vis}) + \frac{1}{2} s_{pose} \\
 & + e^{-s_{act}} \cdot L_{CE}(y_{class}, \hat{y}_{class}) + \frac{1}{2} s_{act} \\
 & + \lambda_{geom} \times L_{Gaussian}
 \end{aligned}$$

Coming from, Gaussian itself:

$$p(y_i | f(x), \sigma_i) = \frac{1}{\sqrt{2\pi\sigma_i^2}} \exp\left(-\frac{\|y_i - f(x)\|^2}{2\sigma_i^2}\right)$$

Where:

- $y_i$  = ground truth for task  $i$
- $f(x)$  = model's prediction
- $\sigma_i$  = learned noise/uncertainty for task  $i$

$$-\log p(y_i | f(x), \sigma_i) = \frac{1}{2\sigma_i^2} \|y_i - f(x)\|^2 + \frac{1}{2} \log(\sigma_i^2)$$

$s_i = \log(\sigma_i^2)$  (this makes  $\sigma_i$  always positive):

$$-\log p(y_i | f(x), s_i) = \frac{1}{2} e^{-s_i} \|y_i - f(x)\|^2 + \frac{s_i}{2}$$

This is where our formula come from:

$$\underbrace{e^{-s_i}}_{\text{automatic weight}} \times \underbrace{L_i}_{\text{task loss}} + \underbrace{\frac{s_i}{2}}_{\text{regularization}}$$

- $s_i = \log(\sigma_i^2) = \log\text{-variance}$
- $\sigma_i$  = the noise/uncertainty the model thinks this task has
- Larger  $\sigma_i \rightarrow$  task is harder/noisier  $\rightarrow$  should get less weight
- Smaller  $\sigma_i \rightarrow$  task is easier/cleaner  $\rightarrow$  should get more weight

Variable 1:

### Why exponential?

- We need  $\sigma_i^2$  in the denominator from the Gaussian formula

$$-e^{-s_i} = e^{-\log(\sigma_i^2)} = \frac{1}{\sigma_i^2}$$

- So high uncertainty  $\rightarrow$  low weight, low uncertainty  $\rightarrow$  high weight

$$\text{Loss: } -e^{-s_i} L_i + \frac{1}{2} = 0 \implies e^{-s_i} L_i = \frac{1}{2}$$

$$\ln(e^{-s_i} L_i) = \ln(0.5) \rightarrow -s_i + \ln(L_i) = -\ln(2) \rightarrow s_{root} = \ln(2 \cdot L_i)$$

Example:

if the loss for detection is 0.303 then  $\rightarrow s = \ln(2 \cdot 0.303) \approx -0.5$

$$s_{det} = -0.5:$$

$$\rightarrow \sigma_{det}^2 = e^{(-0.5)} = 0.606$$

$$\rightarrow weight = e^{(-(-0.5))} = e^{0.5} = 1.649$$

$\rightarrow$  Interpretation: Detection is reliable, give it high weight

if the loss for pose is 1.660 then  $\rightarrow s = \ln(2 \cdot 1.660) \approx 1.2$

$$\text{If } s_{pose} = 1.2:$$

$$\rightarrow \sigma_{pose}^2 = e^{1.2} = 3.320$$

$$\rightarrow weight = e^{(-1.2)} = 0.301$$

$\rightarrow$  Interpretation: Pose is noisy, give it low weight

$$\text{Gradient} = \underbrace{-e^{-s_{det}} \cdot \text{Loss}_{box}}_{\text{Push to increase } s} + \underbrace{0.5}_{\text{Push to decrease } s}$$

$$s_{new} = s_{old} - (\text{Learning Rate} \times \text{Gradient})$$

Why We Chose Each Loss Function

Loss 1: Wise-IoU v3 for Detection

### Why NOT standard IoU?

Standard IoU loss:  $L = 1 - IoU$

Problem: Treats all misalignments equally.

- Box slightly off-center but correct size: Loss  $\approx 0.3$

- Box correct center but wrong size: Loss  $\approx 0.3$
- Box far away and wrong size: Loss  $\approx 0.8$

**Wise-IoU adds two key improvements:**

**1. Distance Attention ( $R_{WIoU}$ ):**

$$R_{WIoU} = \exp\left(\frac{d_{center}^2}{d_{diagonal}^2}\right)$$

Where:

- $d_{center}$  = distance between predicted and ground truth centers
- $d_{diagonal}$  = diagonal of the smallest enclosing box

**Effect:**

Boxes far apart get exponentially higher loss gradient, encouraging the model to move them closer first before fine-tuning size.

**2. Dynamic Non-Monotonic Focusing:**

$$\beta = \frac{L_{IoU}^{(i)}}{\text{mean}(L_{IoU})}$$

IoU = intersection/union = 2640/3728 = 0.708

Loss\_base = 1 - 0.708 = 0.292

Center distance =  $\sqrt{((212-210)^2 + (335-330)^2)} = 5.39$  pixels

Diagonal<sup>2</sup> =  $(\max(212+19, 210+17.5) - \min(212-19, 210-17.5))^2 + \dots = 9856$

$R_{WIoU} = \exp(5.39^2/9856) = \exp(0.00295) = 1.003$

$\beta = 0.292 / 0.25 = 1.168$  (harder than batch average)

Grad\_gain =  $1.003^{1.168} = 1.0035$

L\_WIoU =  $1.0035 \times 0.292 = 0.293$

Loss 2: Wing Loss for Pose Estimation

**The Formula:**

$$L_{Wing}(x) = \begin{cases} \omega \ln(1 + |x|/\epsilon) & \text{if } |x| < \omega \\ |x| - C & \text{if } |x| \geq \omega \end{cases}$$

where  $C = \omega - \omega \ln(1 + \omega/\epsilon)$  ensures continuity.

**Parameters we use:**

$\omega = 10, \epsilon = 2$

implementation operates in **Normalized Coordinate Space [0, 1]**

- Keypoint coordinates normalized to [0, 1]
- Example error:  $|x| = 0.015$  (1.5% of image width)
- Wing Loss:  $10 \times \ln(1 + 0.015/2) = 0.0747$
- With 100× scaling:  $0.0747 \times 100 = 7.47$
- Plus visibility (10×):  $\sim 0.70$

**Training logs show: Pose Loss  $\approx 8.17$**

- Same error converted to pixels:  $0.015 \times 640 = 9.6$  pixels

**PCK@0.1 = 96.77%**

Gradient

**For large errors**

( $|x| \geq \omega = 10$  in pixel space, or  $|x| \geq 0.015$  in normalized space):

— Acts like L1:  $L = |x| - C$

— Gradient:  $\frac{dL}{dx} = \pm 1$

— Effect: Stable, doesn't explode like L2

For **small errors**

( $|x| < \omega$ , typical case in normalized space):

- Acts like logarithmic:  $L = \omega \ln(1 + |x|/\epsilon)$

- Gradient:  $\frac{dL}{dx} = \frac{\omega}{\epsilon + |x|}$

- Effect: Gradient INCREASES as error decreases!

**Gradient amplification example (Normalized Space [0,1]):**

At  $|x| = 0.05$ : gradient =  $10/(2+0.05) = 4.88$

At  $|x| = 0.01$ : gradient =  $10/(2+0.01) = 4.98$

At  $|x| = 0.001$ : gradient =  $10/(2+0.001) = 4.998$

**Why this achieves 96.77% PCK@0.1:**

- PCK@0.1 means "within 10% of torso length"  $\approx 17$  pixels
- In normalized space, most errors are  $< 0.03$  after initial convergence
- Wing Loss aggressively pushes these toward sub-pixel accuracy
- Standard L1 would plateau because gradient stays constant

Average keypoint error = 0.015 in normalized space [0,1]

(This equals  $\sim 9.6$  pixels in 640px image, for reference)

$$L_{Wing} = 10 \times \ln(1 + 0.015/2) = 10 \times \ln(1.0075) = 10 \times 0.00747 = 0.0747$$

Visibility errors: 2 keypoints predicted visible but actually occluded

BCE per keypoint  $\approx 0.035$

$$L_{vis} = 2 \times 0.035 = 0.07$$

With scaling factors ( $100 \times$  Wing [normalization],  $10 \times$  Vis[error encounter]):

$$L_{pose} = 100 \times 0.0747 + 10 \times 0.07 = 7.47 + 0.70 = 8.17$$

Loss 3: CrossEntropy for Activity Classification

**The Formula:**

$$L_{CE} = - \sum_{c=1}^C y_c \log(\hat{y}_c)$$

where:

-  $y_c$  = ground truth (1 for correct class, 0 otherwise)

-  $\hat{y}_c$  = predicted probability (after softmax)

Prediction: [0.85, 0.08, 0.04, 0.02, 0.01, 0.00]

Ground truth: class 0 (checking\_left)

$$L_{CE} = -\log(0.85) = 0.163$$

Loss 4: Gaussian Heatmap for Geometric Guidance

**Why geometric guidance?**

Our insight: Worker activities create spatial relationships.

- "checking\_left" & "storing"  $\rightarrow$  bottle is typically x cm left of wrist

- "checking\_left" → bottle is typically x cm left of wrist
- "rotation" → bottle is centered in front

#### The approach:

Given:

- Predicted keypoints (from pose head)
- Predicted activity (from activity head)
- Statistical priors:  $\mu_{activity} = (offset_x, offset_y), \sigma_{activity}$

We compute the expected bottle location and create a Gaussian heatmap:

$$G_{expected}(x, y) = \exp\left(-\frac{(x-x_{expected})^2 + (y-y_{expected})^2}{2\sigma^2}\right)$$

Then compare with predicted objectness:

$$L_{Gaussian} = \text{MSE}(\sigma(objectness_{pred}), G_{expected})$$

Expected location creates Gaussian with  $\sigma=15$  pixels

Actual detection 5.39 pixels away

$$\begin{aligned} G_{expected} &= \exp\left(-\frac{d^2}{2\sigma^2}\right) \\ &= \exp\left(-\frac{5.39^2}{2 \cdot 15^2}\right) \\ &= \exp\left(-\frac{29.0521}{450}\right) \\ &= \exp(-0.06456) \\ &\approx \mathbf{0.9375} \end{aligned}$$

$$\begin{aligned} Loss_{geo} &= (\text{Predicted} - \text{Target})^2 \\ &= (0.950 - 0.9375)^2 \\ &= (0.0125)^2 \\ &\approx \mathbf{0.000156} \end{aligned}$$

$$s_{act} = \ln(2 \times 0.163) = \ln(0.326) \approx \mathbf{-1.12}$$

$$s_{det} = \ln(2 \times 0.293) = \ln(0.586) \approx \mathbf{-0.53}$$

$$s_{pose} = \ln(2 \times 8.17) = \ln(16.34) \approx \mathbf{2.79}$$

$$w_{det} = e^{-(-0.53)} = e^{0.53} \approx \mathbf{1.699}$$

$$w_{pose} = e^{-2.79} \approx \mathbf{0.061}$$

$$w_{act} = e^{-(-1.12)} = e^{1.12} \approx \mathbf{3.065}$$

$$\begin{aligned} L_{total} &= (1.699 \times 0.293) + (0.061 \times 8.17) + (3.065 \times 0.163) + 0.57 + (0.3 \times 0.000156) \\ &\approx 0.5 + 0.5 + 0.5 + 0.57 + 0.0000468 \\ &\approx \mathbf{2.070} \end{aligned}$$

### Key Findings:

1. Geometric guidance HURTS detection (61.02% with geom=1.0 vs 68.66% with geom=0.0)
2. Even without geometric loss, neural detection caps at 68.66%

Why hurting?

- **Error Propagation**
  - If pose prediction is wrong → expected bottle location is wrong
  - Geometric loss then penalizes CORRECT detections that are far from WRONG expected location
- **Overfitting to Statistics**
  - Statistical priors computed on training data
  - Test workers with different behaviors → learned distribution doesn't generalize
- **Model Already Knew This**
  1. **Remove Geometric Loss (Empirically Validated)**
- Time faster →
